High Current Temperature Sensitive Roll-to-Roll Printed Transistor

Francesco Pastorelli¹

¹ Technical University of Denmark Roskilde Denmark

 Hide Abstract

Organic thin film transistors (OTFT) offer great potential for use in flexible electronics. Much of this potential lies in the solution processability of the organic polymers enabling both roll coating and printing on flexible substrates and thus greatly reducing the material and fabrication costs. We have fabricated an OTFT in ambient air, on a PET flexible substrate. The printing technique is very similar to the one used for printing newspapers and has low environmental impact in comparison with traditional electronics. This is because it is made at lower temperature than you would normally use for baking a cake. After implementing the transistor we build a small demonstrator circuit to operate a printed electrochromic surface powered by an organic solar cell all realized with the same technique. The devices have top gate architecture and were completed by slot-die coating of the organic semiconductor poly-3-hexylthiophene and the dielectric material polyvinylphenol before the gate was applied by screen printing. We explore the footprint and the practically accessible geometry of such devices with a special view toward being able to drive large currents while handling the thermal aspects. We find especially that an elevated operational temperature is beneficial with respect to both transconductance and on/off ratio. We achieve high currents of up to 45 mA at a temperature of 80 °C with an on/off ratio of 100. We observe a significant temperature dependence of the performance which can be explored further in sensing applications.
